

Recapitulation: Density operators

- One particle $n(r) = \langle \sum_i \delta(r - r_i) \rangle$
- Two particle $n(r, r') = \langle \sum_{i \neq j} \delta(r - r_i) \delta(r' - r_j) \rangle$,
the correlation of a particle with other particles.
- Pair correlation function $g(r, r') = \frac{n(r, r')}{n(r)n(r')}$
- A typical W is the Lennard-Jones (L J) potential:
- $w(r) = w_0 \left[\left(\frac{r}{\sigma} \right)^{12} - \left(\frac{r}{\sigma} \right)^6 \right]$

Recapitulation: the compressibility χ and the equation of state:

$$n kT \chi = \frac{kT}{\partial p / \partial n} = 1 + n \int d^3r (g - 1)$$

$$P = nkT - n^2 \int d^3r g(r) r \frac{\partial U(r)}{\partial r} / 6$$

Pair correlation function can be measured experimentally

- Pair correlation function $g(r, r') = \frac{n(r, r')}{n(r)n(r')}$
- In scattering experiments, one can measure
- $S(k) = \sum \exp(ik \cdot r_{jl}) / N$
- $S(k) = \int \frac{dr dr'}{N} \langle n(r)n(r') \rangle e^{i k(r-r')} = 1 + n \int (g - 1) e^{i k(r-r')} dr$
- The compressibility $n kT \chi = \frac{kT}{\partial p / \partial n} = 1 + n \int d^3r (g - 1)$ can be related to the zero q limit of S(q)!

- The experiments measure the **static structure factor** $S(\vec{q})$

$$S(\vec{q}) \equiv \frac{1}{N} \langle \hat{n}_1(\vec{q}) \hat{n}_1(-\vec{q}) \rangle - N \delta_{\vec{q},0},$$

in which the last term is introduced for later convenience (recall that the scattered beam cannot be measured at exactly $\vec{q} = 0$).

- $S(\vec{q})$ is related to the **pair distribution function** $g(\vec{r})$ for a continuous phase by

$$S(\vec{q}) - 1 = \frac{N}{V} \int d^3r [g(\vec{r}) - 1] \exp(-i\vec{q} \cdot \vec{r}).$$

- That is, $S(\vec{q}) - 1$ is the Fourier transform of $n[g(\vec{r}) - 1]$.

Typical forms of $S(\vec{q})$

- What do we expect to obtain from measurements of $S(\vec{q})$?
- Let us survey some typical results for gases, liquids, and crystals of spherically symmetric atoms.

$$S(q) = 1 - 4\pi n \left(\frac{\sin q\sigma - q\sigma \cos q\sigma}{q^3} \right) + O(n^2).$$

- In the limit of an ideal gas (i.e., $n \rightarrow 0$), we have

$$S(q) \rightarrow 1.$$

- Deviations of $S(q)$ from 1 therefore give a measure of how far the system deviates from an ideal gas.

- Significance

- The special values of \vec{q} where the peaks occur are those values satisfying

$$\exp(i\vec{q} \cdot \vec{R}) = 1$$

for all lattice vectors \vec{R} of the crystal lattice.

- These values of \vec{q} are just the **reciprocal lattice** vectors \vec{K} .

Order parameter for solid

$$\text{density } \rho(r) = \sum_i \delta(r - r_i)$$

Fourier transform

$$\rho(q) = \int dr \rho(r) e^{iq \cdot r} / N = \sum_j e^{iq \cdot r_j} / N$$

For solids, there are vectors G so that $G \cdot R_j = 2\pi n$ for some integer n .

For example, in one dimension, for $R_j = ja$, $G = 2\pi/a$

$\rho(G) = \sum_j e^{iG \cdot u_j} / N$ is a good order parameter.

$$\rho(G) = \sum_j e^{iG \cdot u_j} / N$$

Average of the order parameter

- $\langle \rho(G) \rangle = \sum_j \langle e^{iG \cdot u_j} \rangle / N$
- Use cumulant expansion:
- $\langle e^{if} \rangle \cong e^{-\frac{\langle f^2 \rangle}{2} + \dots}$ for any function f such that $\langle f \rangle = 0$.
- This can be seen by comparing the series expansion on both sides.
- $\langle \rho(G) \rangle \cong \sum_j e^{-\langle [G \cdot u_j]^2 \rangle / 2} / N$.
- For fluids $\langle u^2 \rangle = \infty$, $\langle \rho(G) \rangle = 0$

Fluctuation of the order parameter

- $\langle |\rho(G)|^2 \rangle = \sum_{j,k} \langle e^{iG \cdot (u_j - u_k)} \rangle$
- Use cumulant expansion:
- $\langle e^{if} \rangle \cong e^{-\frac{\langle f^2 \rangle}{2} + \dots}$ for any function f such that $\langle f \rangle = 0$.
- This can be seen by comparing the series expansion on both sides.
- $\langle |\rho(G)|^2 \rangle / N^2 \cong \sum_j e^{-\langle [G \cdot (u_0 - u_j)]^2 \rangle / N}$

FIG. 5. The argon intensity function $i(s)$ at $t = -120^\circ\text{C}$.

- How can we understand the divergence in scattering for a fluid near the critical point?
- We have proved the following theorem for the structure factor at long wavelengths:

$$\lim_{q \rightarrow 0} S(q) = nk_B T K_T,$$

where K_T is the isothermal compressibility

$$K_T \equiv -\frac{1}{V} \left(\frac{\partial V}{\partial P} \right)_T.$$

- This is just the inverse of the isothermal bulk modulus

$$B_T \equiv -V \left(\frac{\partial P}{\partial V} \right)_T = \frac{1}{K_T}.$$

- In an ordinary liquid far from the critical point, the order of magnitude of these quantities is

$$B_T \sim 30000 \text{ atm}, \quad B_T^{\text{id}} \sim 1000 \text{ atm}; \quad \therefore \lim_{q \rightarrow 0} S(q) \sim 0.03.$$

- However, at the critical point (T_c, P_c) , we have $\partial P / \partial V = 0$ and thus $B_T = 0$ (i.e., $K_T \rightarrow \infty$); consequently,

$$\lim_{q \rightarrow 0} S(q) = \infty.$$

Significance

Scattering experiment
Nature of experiment
Interaction between
probe and system
Interaction matrix
element
Fourier transform of v
One-particle density
Static structure factor
Typical forms of $S(\vec{q})$
Dilute gas
Liquid structure factor
Distribution function
Critical point
Crystal structure factor
Reciprocal lattice
Temperature variation
Molecular dynamics
Range of correlations
Scattering divergence
near critical point
Compressibility rule
Derivation of
compressibility rule
One-particle density
Average values
Variance of N
Pair distribution function
Structure factor
Significance

- What is the significance of this result?

$$\lim_{q \rightarrow 0} S(q) = \frac{K_T}{K_T^{\text{id}}}$$

- On the left side, $S(q)$ is a microscopic quantity describing the structural order in a fluid.
- On the right side are thermodynamic quantities.

Significance

- What is the significance of this result?

$$\lim_{q \rightarrow 0} S(q) = \frac{K_T}{K_T^{\text{id}}}$$

- On the left side, $S(q)$ is a microscopic quantity describing the structural order in a fluid.
- On the right side are thermodynamic quantities.
- In a typical liquid far from the critical point, the value of this ratio is much less than one.
- However, it diverges near the critical point, where $K_T \rightarrow \infty$.

- On the right side are thermodynamic quantities.
- In a typical liquid far from the critical point, the value of this ratio is much less than one.
- However, it diverges near the critical point, where $K_T \rightarrow \infty$.
- Since $S(q) - 1$ is the Fourier transform of $n[g(r) - 1]$, a divergence of $S(q)$ at long wavelengths

$$\lambda = \frac{2\pi}{q}$$

Pair correlation function can be measured experimentally

- Pair correlation function $g(r, r') = \frac{n(r, r')}{n(r)n(r')}$
- In scattering experiments, one can measure
- $S(k) = \sum \exp(ik \cdot r_{jl}) / N$
- $S(k) = \int \frac{dr dr'}{N} \langle n(r)n(r') \rangle e^{i k(r-r')} = 1 + n \int (g - 1) e^{i k(r-r')} dr$
- The compressibility $n kT \chi = \frac{kT}{\partial p / \partial n} = 1 + n \int d^3r (g - 1)$ can be related to the zero q limit of S(q)!

- Current plan for the last two weeks in class is to have students form groups by themselves, perform simulations with the computer programs I shall give them and present their results during class in either Chinese or English.

Do you know how to compile and run a computer program

- (1) Yes
- (2) No

Do you know the programming language

- (1) Fortran
- (2) C
- (3) others
- (4) no
